Abstract

Software is one of the most powerful tools that we humans have at our disposal; it allows a skilled programmer to interact with the world in complex and profound ways. At the same time, thanks to improvements in large language models (LLMs), there has also been a rapid development in AI agents that interact with and affect change in their surrounding environments. In this paper, we introduce OpenDevin, a platform for the development of powerful and flexible AI agents that interact with the world in similar ways to those of a human developer: by writing code, interacting with a command line, and browsing the web. We describe how the platform allows for the implementation of new agents, safe interaction with sandboxed environments for code execution, coordination between multiple agents, and incorporation of evaluation benchmarks. Based on our currently incorporated benchmarks, we perform an evaluation of agents over 15 challenging tasks, including software engineering (*e.g.*, SWE-BENCH) and web browsing (*e.g.*, WEBARENA), among others. Released under the permissive MIT license, OpenDevin is a community project spanning academia and industry with more than 1.3K contributions from over 160 contributors and will improve going forward.

1 Introduction

Powered by large language models (LLMs; [5, 20, 40, 60]), user-facing AI systems (such as ChatGPT) have become increasingly capable of performing complex tasks such as accurately responding to user queries, solving math problems, and generating code. In particular, AI *agents*, systems that can perceive and act upon the external environment, have recently received ever-increasing research focus. They are moving towards performing complex tasks such as developing software [21], navigating real-world websites [79], doing household chores [1], or even performing scientific research [4, 56].

As AI agents become capable of tackling complex problems, their development and evaluation have also become challenging. There are numerous recent efforts in creating open-source frameworks that facilitate the development of agents [7, 16, 67]. These agent frameworks generally include: 1) **interfaces** through which agents interact with the world (such as JSON-based function calls or code execution), 2) **environments** in which agents operate, and 3) **interaction mechanisms** for

Preprint. Under review.

human-agent or agent-agent communication. These frameworks streamline and ease the development process in various ways (Tab. 1, §C).

When designing AI agents, we can also consider how *human* interacts with the world. The most powerful way in which humans currently interact with the world is through *software* – software powers every aspect of our life, supporting everything from the logistics for basic needs to the advancement of science, technology, and AI itself. Given the power of software, as well as the existing tooling around its efficient development, use, and deployment, it provides the ideal interface for AI agents to interact with the world in complex ways. However, building agents that can effectively develop software comes with its own unique challenges. How can we enable agents to effectively *create and modify code in complex software systems*? How can we provide them with tools to *gather information on-the-fly* to debug problems or gather task-requisite information? How can we ensure that development is *safe and avoids negative side effects* on the users' systems?

In this paper, we introduce OpenDevin, a community-driven platform designed for the development of generalist and specialist AI agents that interact with the world through software.[1] It features:

(1) An **interaction mechanism** which allows user interfaces, agents, and environments to interact through a *event stream* architecture that is powerful and flexible (§2.1).
(2) An **environment** that consists of a sandboxed operating system and a web browser that the agents can utilize for their tasks (§2.2).
(3) An **interface** allowing the agent to interact with the environment in a manner similar to actual software engineers (§2.3). We provide the capability for agents to (a) create complex software, (b) execute the code, and (c) browse websites to collect information.
(4) **Multi-agent delegation**, allowing multiple specialized agents to work together (§2.4).
(5) **Evaluation framework**, facilitating the evaluation of agents across a wide range of tasks (§4).

Importantly, OpenDevin is not just a conceptual framework, but it also includes a comprehensive and immediately usable implementation of agents, environments, and evaluations. As of this writing, OpenDevin includes an agent hub with over 10 implemented agents (§3), including a strong generalist agent implemented based on the CodeAct architecture [63], with additions for web browsing [52] and code editing [72]. Interaction with users is implemented through a chat-based user interface that visualizes the agent's current actions and allows for real-time feedback (Fig. 1, §D). Furthermore, the evaluation framework currently supports 15 benchmarks, which we use to evaluate our agents (§4).

Released under a permissive MIT license allowing commercial use, OpenDevin is poised to support a diverse array of research and real-world applications across academia and industry. OpenDevin has gained significant traction, with 28K GitHub stars and more than 1.3K contributions from over 160 contributors. We envision OpenDevin as a catalyst for future research innovations and diverse applications driven by a broad community of practitioners.

2 OpenDevin Architecture

We describe, using OpenDevin, (1) how to define and implement an agent (§2.1), (2) how each action execution leads to an observation (§2.2), (3) how to reliably manage and extend commonly used skills for agents (§2.3), and (4) how to compose multiple agents together for task solving (§2.4). Fig. 3 provides an overview.

2.1 Agent Definition and Implementation

An **agent** can perceive the **state** of the environment (*e.g.*, prior actions and observations) and produce an **action** for execution while solving a user-specified task.

The State and Event Stream. In OpenDevin, the state is a data structure that encapsulates all relevant information for the agent's execution. A key component of this state is the **event stream**, which is a chronological collection of past actions and observations, including the agent's own actions and user interactions (*e.g.*, instructions, feedback). However, the state extends beyond just the event stream. It

[1]While initially inspired by the AI software engineer Devin [9], OpenDevin has quickly evolved to support a much wider range of applications beyond software engineering through diverse community contributions.

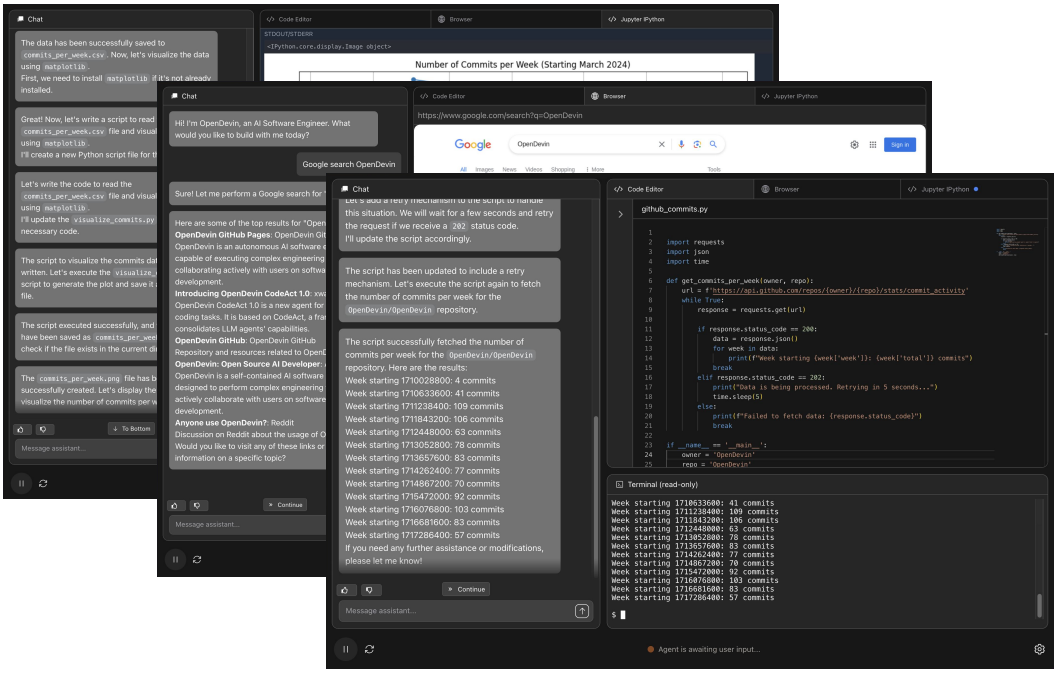

Figure 1: OpenDevin User Interface (UI, §D) allows users to view files, check executed bash commands/Python code, observe the agent's browser activity, and directly interact with the agent.

also incorporates auxiliary information for agent's operation, such as the accumulative cost of LLM calls, metadata to track multi-agent delegation (§2.4), and other execution-related parameters.

Actions. Inspired by CodeAct [63], OpenDevin connects an agent with the environment through a core set of general actions. Actions `IPythonRunCellAction` and `CmdRunAction` enable the agent to execute *arbitrary* Python code and bash commands inside the sandbox environment (*e.g.*, a securely isolated Linux operating system). `BrowserInteractiveAction` enables interaction with a web browser with a domain-specific language for browsing introduced by BrowserGym [12]. The action space based on programming languages (PL) is powerful and flexible enough to perform any task with tools in different forms (*e.g.*, Python function, REST API, *etc.*) [63] while being reliable and easy to maintain.

Figure 2: Minimal example of implementing an agent in OpenDevin.

```python
class MinimalAgent:
    def reset(self) -> None:
        self.system_message = "You are a helpful assistant ..."

    def step(self, state: State):
        messages: list[dict[str, str]] = [
            {'role': 'system', 'content': self.system_message}
        ]
        for prev_action, obs in state.history:
            action_message = get_action_message(prev_action)
            messages.append(action_message)
            obs_message = get_observation_message(obs)
            messages.append(obs_message)

        # use llm to generate response (e.g., thought, action)
        response = self.llm.do_completion(messages)

        # parse and execute action in the runtime
        action = self.parse_response(response)
        if self.is_finish_command(action):
            return AgentFinishAction()
        elif self.is_bash_command(action):
            return CmdRunAction(command=action.command)
        elif self.is_python_code(action):
            return IPythonRunCellAction(code=action.code)
        elif self.is_browser_action(action):
            return BrowseInteractiveAction(code=action.code)
        else:
            return MessageAction(content=action.message)
```

This design is also compatible with existing tool-calling agents that require a list of pre-defined tools [6]. That is, users can easily define tools using PL supported in OpenDevin primitive actions (*e.g.*, write a Python function for calculator) and make those tools available to the agent through JSON-style function-calling experiences [49]. Moreover, the framework's powerful PL-based primitives further make it possible for the agents to create tools by themselves (*e.g.*, by generating Python functions [75]) when directly relevant APIs to complete the task are unavailable. Refer to §2.3 for how these core PL-based actions can be composed into a diverse set of tools.

Observations. Observations describe environmental changes that the agent observes. It may or may not be caused by the agent's action: It can be either 1) natural language messages from the user

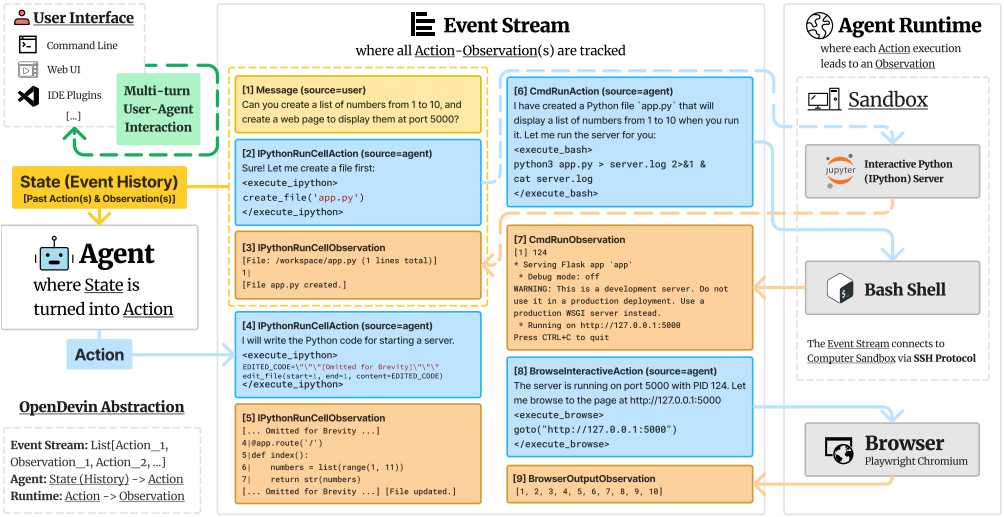

Figure 3: OpenDevin consists of 3 main components: 1) **Agent abstraction** where community can contribute different implementation of agents (§2.1) into an Agent Hub (§3); 2) **Event stream** for tracking history of actions and observations; 3) **Agent runtime** to execute all agent actions into observations (§2.2).

instructing agents to perform certain tasks, 2) the execution outcome of the agent's previous action (*e.g.*, code execution result, an accessibility tree [35], a screenshot of the web page, *etc.*).

Implement a New Agent. The agent abstraction is designed to be simple yet powerful, allowing users to create and customize agents for various tasks easily. The core of the agent abstraction lies in the `step` function, which takes the current state as input and generates an appropriate action based on the agent's logic. Simplified example code for the agent abstraction is illustrated in Fig. 2. By providing this abstraction, OpenDevin allows the users to focus on defining desired agent behavior and logic without worrying about the low-level details of how actions are executed (§2.2).

2.2 Agent Runtime: How Execution of Actions Results in Observations

Agent Runtime provides a general environment that equips the agent with an action space comparable to that of human software developers, enabling OpenDevin agents to tackle a wide range of software development and web-based tasks, including complex software development workflows, data analysis projects, web browsing tasks, and more. It allows the agent to access a bash terminal to run code and command line tools, utilize a Jupyter notebook for writing and executing code on-the-fly, and interact with a web browser for web-based tasks (*e.g.*, information seeking).

Linux SSH Sandbox. For each task session, OpenDevin spins up a securely isolated docker container sandbox, where all the bash commands from the agent are executed. OpenDevin connects to the sandbox through SSH protocol, executes arbitrary commands from the agent, and returns the execution results as observations to the agent. A configurable workspace directory containing files the user wants the agent to work on is mounted into that secure sandbox for OpenDevin agents to access.

Jupyter IPython. The Linux sandbox also supports running an interactive Jupyter server, which can be used by the agent for interactive *python* code execution [19] and debugging.

Web Browser. OpenDevin implements a Chromium browser based on Playwright [47]. It interfaces with agents using a set of browser action primitives defined by BrowserGym [12, 52], such as navigation, clicking, typing, scrolling. The full set of actions is detailed in §I. After executing these actions, the browser runtime provides a rich set of observations about the current state of the browser, including HTML, DOM, accessibility tree [35], screenshot, opened tabs, *etc*. These observations can be also augmented with configurable attributes that could allow agents to better understand web page observations, such as using a set-of-marks on screenshot [15, 71], visible element marking, focused element, interactable element marking, in-viewport element filtering [79], *etc*.

Table 1: Comparison of different AI agent frameworks (§C). SWE refers to 'software engineering'. **Standardized tool library**: if framework contains reusable tools for different agent implementations (§2.3); **Built-in sandbox & code execution**: if it supports sandboxed execution of arbitrary agent-generated code; **Built-in web browser**: if it provides agents access to a fully functioning web browser; **Human-AI collaboration**: if it enables multi-turn human-AI collaboration (*e.g.*, human can interrupt the agent during task execution and/or provide additional feedback and instructions); **AgentHub**: if it hosts implementations of various agents (§3); **Evaluation Framework**: if it offers systematic evaluation of implemented agents on challenging benchmarks (§4); **Agent QC** (Quality Control): if the framework integrates tests (§E) to ensure overall framework software quality.

* No native support. Third-party commercial options are available.

2.3 Agent Skills: The Extensible Agent-Computer Interface

SWE-Agent [72] highlights the importance of a carefully crafted Agent-Computer Interface (ACI, *i.e.*, specialized tools for particular tasks) in successfully solving complex tasks. However, creating, maintaining, and distributing a wide array of tools can be a daunting engineering challenge, especially when we want to make these tools available to different implementations of agents (§3). To tackle these, we build an **AgentSkills library**, a toolbox designed to enhance the capabilities of agents, offering utilities not readily available through basic *bash* commands or *python* code.

Easy to create and extend tools. AgentSkills is designed as a Python package consisting of different utility functions (*i.e.*, tools) that are automatically imported into the Jupyter IPython environment (§2.2). The ease of defining a Python function as a tool lowers the barrier for community members to contribute new tools to the skill library. The generality of Python packages also allows different agent implementations to easily leverage these tools through one of our core action `IPythonRunCellAction` (§2.1).

Rigorously tested and maintained. We follow best practices in software engineering and write extensive unit tests for tools in AgentSkills to ensure their reliability and usability.

Inclusion criteria and philosophy. In the AgentSkills library, we do not aim to wrap every possible Python package and re-teach agents their usage (*e.g.*, LLM already knows `pandas` library that can read CSV file, so we don't need to re-create a tool that teaches the agent to read the same file format). We only add a new skill when: (1) it is not readily achievable for LLM to write code directly (*e.g.*, edit code and replace certain lines), and/or (2) it involves calling an external model (*e.g.*, calling a speech-to-text model, or model for code editing [51]).

Currently supported skills. AgentSkills library includes file editing utilities adapted from SWE-Agent [72] like `edit_file`, which allows modifying an existing file from a specified line; scrolling functions `scroll_up` and `scroll_down` for viewing a different part of files. It also contains tools that support reading multi-modal documents, like `parse_image` and `parse_pdf` for extracting information from images using vision-language models (*e.g.*, GPT-4V) and reading text from PDFs, respectively. A complete list of supported skills can be found in §H.

2.4 Agent Delegation: Cooperative Multi-agent Interaction

OpenDevin allows interactions between multiple agents as well. To this end, we use a special action type `AgentDelegateAction`, which enables an agent to delegate a specific subtask to another agent. For example, the generalist CodeActAgent, with limited support for web-browsing, can use `AgentDelegateAction` to delegate web browsing tasks to the specialized BrowsingAgent to perform more complex browsing activity (*e.g.*, navigate the web, click buttons, submit forms, *etc.*).

3 AgentHub: A Hub of Community-Contributed Agents

Based on our agent abstraction (§2.1), OpenDevin supports a wide range of community-contributed agent implementations for end users to choose from and act as baselines for different agent tasks.

CodeAct Agent. CodeActAgent is the default generalist agent based on the CodeAct framework [63]. At each step, the agent can (1) converse to communicate with humans in natural language to ask for clarification, confirmation, *etc*., or (2) to perform the task by executing code (*a.k.a.*, **CodeAct**), including executing bash commands, Python code, or browser-specific programming language (§2.2). This general action space allows the agent (v1.5 and above) to perform various tasks, including editing files, browsing the web, running programs, etc.

Browsing Agent. We implemented a generalist web agent called Browsing Agent, to serve as a simple yet effective baseline for web agent tasks. The agent is similar to that in WebArena [79], but with improved observations and actions, with only zero-shot prompting. At each step, the agent prompts the LLM with the task description, browsing action space description, current observation of the browser using accessibility tree, previous actions, and an action prediction example with chain-of-thought reasoning. The expected response from the LLM will contain chain-of-thought reasoning plus the predicted next actions, including the option to finish the task and convey the result to the user. Full prompts are in §J. It can be extended to create more capable web agents, or called by other agents through delegation (§2.4) to enable browsing capability.

GPTSwarm Agent. GPTSwarm [83] pioneers the use of optimizable graphs to construct agent systems, unifying language agent frameworks through modularity. Each node represents a distinct operation, while edges define collaboration and communication pathways. This design allows automatic optimization of nodes and edges, driving advancements in creating multi-agent systems.

Micro Agent(s). In addition, OpenDevin enables the creation of **micro agent**, an agent *specialized* towards a particular task. A micro agent re-uses most implementations from an existing generalist agent (e.g., CodeAct Agent). It is designed to lower the barrier to agent development, where community members can share specialized prompts that work well for their particular use cases. Without programming, a user can create a micro agent by providing the agent's name, description, the schema for its inputs and outputs, and optionally a specialized prompt (e.g., example demonstrations showing how to perform a particular task) that gear the generalist agent toward specific tasks, for example, the `CommitWriterAgent` for generating git commit messages, and the `TypoFixerAgent` for correcting typos across the entire code repository.

4 Evaluation

To systematically track progress in building generalist digital agents, as listed in Tab. 2, we integrate 15 established benchmarks into OpenDevin. These benchmarks cover software engineering, web browsing, and miscellaneous assistance. In this section, we compare OpenDevin to open-source reproducible baselines that do not perform manual prompt engineering specifically based on the benchmark *content*. Please note that we use 'OD' as shorthand for OpenDevin for the rest of this section for brevity reasons.

Table 2: Evaluation benchmarks in OpenDevin.

Category	Benchmark	Required Capability
Software	SWE-Bench [21]	Fixing Github issues
	HumanEvalFix [37]	Fixing Bugs
	BIRD [27]	Text-to-SQL
	BioCoder [58]	Bioinformatics coding
	ML-Bench [57]	Machine learning coding
	Gorilla APIBench [46]	Software API calling
	ToolQA [81]	Tool use
Web	WebArena [79]	Goal planning & realistic browsing
	MiniWoB++ [30]	Short trajectory on synthetic web
Misc. Assistance	GAIA [34]	Tool-use, browsing, multi-modality
	GPQA [50]	Graduate-level Google-proof Q&A
	AgentBench [31]	Operating system interaction (bash)
	MINT [64]	Multi-turn math and code problems
	Entity Deduction Arena [77]	State tracking & strategic planning
	ProofWriter [55]	Deductive Logic Reasoning

4.1 Result Overview

In OpenDevin, our goal is to develop **general digital agents** capable of interacting with the world through software interfaces (as exemplified by the code actions described in §2.1). We recognize that a software agent should excel not only in code editing but also in web browsing and various auxiliary tasks, such as answering questions about code repositories or conducting online research.

Table 3: Selected evaluation results for OpenDevin agents (§4). See Tab. 4 (software), Tab. 5 (web), Tab. 6 (miscellaneous assistance) for full results across benchmarks.

* Numbers are reported from CodeActAgent `v1.5`.

Tab. 3 showcases a curated set of evaluation results. While OpenDevin agents may not achieve top performance in every category, they are designed with generality in mind. Notably, the same CodeAct agent, without any modifications to its system prompt, demonstrates competitive performance across three major task categories: software development, web interaction, and miscellaneous tasks. This is particularly significant when compared to the baseline agents, which are typically designed and optimized for specific task categories.

4.2 Software Engineering

Next, we report results specifically for software engineering benchmarks in Tab. 4.

4.2.1 SWE-Bench

SWE-bench [21] is designed to assess agents' abilities in solving real-world GitHub issues, such as bug reports or feature requests. The agent interacts with the repository and attempts to fix the issue provided through file editing and code execution. The agent-modified code repository is tested against a test suite incorporating new tests added from human developers' fixes for the same issue. Each test instance accompanies a piece of "hint text" that consists of natural language suggestions for how to solve the problem. Throughout this paper, we report all results *without using hint text*. A canonical subset, SWE-bench Lite, is created to facilitate accessible and efficient testing. We default to use this subset for testing for cost-saving consideration.[2]

Result. As shown in Tab. 4, our most recent version of CodeActAgent v1.8 generalist, using `claude-3.5-sonnet`, achieves a competitive resolve rate of 26% compared to other open-source agents specialized for software development. We also evaluated CodeActAgent v1.8 using `gpt-4o-mini`. While it only solves 6.3% of the problems, it does so at less than 1% of the cost compared to other models.

4.2.2 HumanEvalFix

HumanEvalFix [37] tasks agents to fix a bug in a provided function with the help of provided test cases. The bugs are created to ensure one or more test cases fail. We focus on the Python subset of

[2]Running the complete set of 2294 instances costs $6.9k, using a conservative estimate of $3 per instance.

the benchmark and allow models to solve the bugs by self-debug over multiple turns, incorporating feedback from test execution. We follow the setup from Muennighoff et al. [37] using pass@k [8].

Results. In Tab. 4, OpenDevin CodeActAgent successfully fixes 79.3% of bugs in the Python split. This is significantly better than all non-agentic approaches, almost doubling the performance of `StarCoder2-15B` [28, 32]. While SWE-Agent achieves 87.7%, Yang et al. [72] provides the model a full demonstration of a successful sample trajectory fixing one of the bugs in the test dataset

("1-shot"), whereas our evaluation of OpenDevin is 0-shot. As HumanEvalFix has been created by humans and all bugs carefully validated, achieving 100% on this benchmark is entirely feasible, which we seek to do in future iterations of OpenDevin.

4.2.3 ML-Bench

ML-Bench [57] evaluates agents' ability to solve machine learning tasks across 18 GitHub repositories. The benchmark comprises 9,641 tasks spanning 169 diverse ML problems, requiring agents to generate bash scripts or Python code in response to user instructions. In the sandbox environment, agents can iteratively execute commands and receive feedback, allowing them to understand the repository context and fulfill user requirements progressively. Following the setup from the original paper, we perform agent evaluation on the quarter subset of ML-Bench.

Results. As shown in Table 4, OpenDevin agents with GPT-4o achieve the highest success rate of 76.47% on ML-Bench, outperforming SWE-Agent (42.64%). Performance drops with less capable models. These results demonstrate the effectiveness of OpenDevin agent in complex ML tasks. We notice that agents show potential in reducing hallucination and syntax errors compared to non-agent approaches in the ML-LLM-Bench settings [57].

4.2.4 Gorilla APIBench

Gorilla APIBench [46] evaluates agents' abilities to use APIs. it incorporates tasks on TorchHub, TensorHub, and HuggingFace. During the evaluation, models are given a question related to API usage, such as "*identify an API capable of converting spoken language in a recording to text*." Correctness is evaluated based on whether the model's API call is in the correct domain.

Results. As shown in Table 4, OpenDevin using GPT-4o, with a success rate of 36.4%, outperforms baselines not specifically finetuned for API calling. While Gorilla shows higher performance on APIBench, Patil et al. [46] finetune this model for API calling in particular.

4.2.5 ToolQA

ToolQA [81] evaluates agents' abilities to use external tools. This benchmark includes tasks on various topics like flight status, coffee price, Yelp data, and Airbnb data, requiring the use of various tools such as text tools, database tools, math tools, graph tools, code tools, and system tools. It features two levels: easy and hard. Easy questions focus more on single tool usage, while hard questions emphasize reasoning. For evaluation, the easy subset is used to assess tool use capabilities.

Results. Compared to all baselines, OpenDevin with GPT-4o shows the highest performance. We notice that agents perform better on tasks related to CSV and database tool usage but requires improvements on math and calculator tool usage.

4.2.6 BioCoder

BioCoder [58] is a repository-level code generation benchmark that evaluates agents' performance on bioinformatics-related tasks, specifically the ability to retrieve and accurately utilize context. The original prompts contain the relevant context of the code; however, in this study, we have removed them to demonstrate the capability of OpenDevin to perform context retrieval, self-debugging, and reasoning in multi-turn interactions. BioCoder consists of 157 Python and 50 Java functions, each targeting a specific area in bioinformatics, such as proteomics, genomics, and other specialized domains. The benchmark targets real-world code by generating code in existing repositories where the relevant code has been masked out.

Results. Table 4 shows that OpenDevin, using GPT-4o, achieves a success rate of 44.0%. This outperforms all prompting-based non-agent baselines, with GPT-4 alone only achieving 6.4%. BioCoder proves to be a particularly challenging benchmark for non-agent methods, as they did not incorporate any repository-level retrieval methods, making these models lack access to crucial repo-level information such as global variables and function declarations.

Table 5: OpenDevin Web Browsing Evaluation Results (§4.3).

Agent	Model	Success Rate (%)	$ Avg. Cost
WebArena [79], 812 instances

OD CodeActAgent v1.8, Generalist. via **delegation** to BrowsingAgent v1.0	`gpt-4o-2024-05-13`	39.8	–

4.2.7 BIRD

BIRD [27] is a benchmark for text-to-SQL tasks (*i.e.*, translate natural language into executable SQL) aimed at realistic and large-scale database environments. We select 300 samples from the dev set to integrate into OpenDevin and evaluate on execution accuracy. Additionally, we extend the setting by allowing the agent to engage in multi-turn interactions to arrive at the final SQL query, enabling it to correct historical results by observing the results of SQL execution.

Results. As shown in Table 4, OpenDevin with GPT-4o achieves an execution accuracy of 47.3% on a subset of BIRD, showcasing the potential of OpenDevin as a SQL agent. The result outperforms approaches utilizing prompting with code LLMs, such as CodeLlama-7B-Instruct (18.3%) and CodeQwen-7B-Chat [3] (31.3%).

4.3 Web Browsing

We report evaluation results for web browsing benchmarks in Tab. 5.

4.3.1 WebArena

WebArena [79] is a self-hostable, execution-based web agent benchmark that allows agents to freely choose which path to take in completing their given tasks. WebArena comprises 812 human-curated task instructions across various domains, including shopping, forums, developer platforms, and content management systems. Each task is paired with a handwritten test case that verifies agent success, *e.g.*, by checking the status of a web page element against a reference or the textual answer returned by the agent.

Results. From Tab. 5, we can see that our BrowsingAgent achieves competitive performance among agents that use LLMs with domain-general prompting techniques. Some agents (e.g., AutoWebGLM) require manual effort tailored to the WebArena task domain. This showcases the performance trade-off between a generalist vs. a domain-tailored specialist web agent, and we opt for a more general browsing agent as a building block in OpenDevin.

4.3.2 MiniWoB

MiniWoB++ [30] is an interactive web benchmark, with built-in reward functions. The tasks are synthetically initialized on 125 different minimalist web interfaces. Unlike WebArena, tasks are easier without page changes, require fewer steps, and provide low-level step-by-step task directions. Note that it contains a portion of environments that require vision capability to tackle successfully,

and many existing work choose to focus only on a subset of the tasks [22, 29, 53]. Still, we report the performance on the full set and only include baselines that are evaluated on the full set.

Results. From Tab. 5 we see that our generalist BrowsingAgent finishes nearly half of the tasks without any adaptation on the environment. However, due to the synthetic nature of MiniWoB++, the state-of-the-art agents explicitly trained for the environments with reinforcement learning and/or human behavior cloning have almost saturated the performance. This shows an even bigger trade-off between generalist and specialist agents than on the more general WebArena benchmark.

4.4 Miscellaneous Assistance

Results for miscellaneous assistance benchmarks are reported in Tab. 6. In particular, we report results for:

4.4.1 GAIA

GAIA [34] evaluates agents' general task-solving skills, covering different real-world scenarios. It requires various agent capabilities, including reasoning, multi-modal understanding, web browsing, and coding. GAIA consists of 466 curated tasks across three levels. Setting up GAIA is traditionally challenging due to the complexity of integrating various tools with the agent, but OpenDevin's infrastructure (*e.g.*, runtime §2.2, tool library §2.3) simplifies the integration significantly.

Results. In our experiments, we achieved a score of 32.1 on the GAIA (level-1 val), significantly improving over the original AutoGPT [14]. GAIA is sensitive to the support of multimodal input and web navigation skills, suggesting further score improvements as OpenDevin's infrastructure improves.

4.4.2 GPQA

GPQA [50] evaluates agents' ability for coordinated tool use when solving challenging graduate-level problems. It consists of 448 curated and difficult multiple-choice questions in biology, physics, and chemistry. Tool use (*e.g.*, python) and web search are often useful to assist agents in answering these questions since they provide accurate calculations that LLMs are often incapable of and access to information outside of the LLM's parametric knowledge base.

Results. Results are shown in Tab. 6 and 7. We observe that OpenDevin's integrated for supporting diverse tool use (*e.g.*, python for calculations) as well as web-search (for searching relevant facts) allows the resulting agent to better solve complex multi-step problems, surpassing the prior *state-of-the-art* by 9.6% and 12.3% on the main and diamond subsets respectively on GPQA [50].

4.4.3 AgentBench

AgentBench [31] evaluates agents' reasoning and decision-making abilities in a multi-turn, open-ended generation setting. We selected the code-grounded operating system (OS) subset with 144 tasks. Agents from OpenDevin interact directly with the task-specific OS using bash commands in a multi-turn manner, combining interaction and reasoning to automate task completion.

Results. In our experiments (Tab. 6), OpenDevin CodeActAgent v1.5 achieves a score of 57.6% on the AgentBench using `gpt-4o`, outperforming the 42.4% baseline using `gpt-4` from the original paper. Interestingly, when employing weaker models such as `gpt-3.5-turbo`, OpenDevin agents generally underperform compared to the original baseline agents. This finding suggests that generalist agents, like those implemented in OpenDevin, require a certain threshold of foundation model capability - particularly instruction following - to function effectively.

4.4.4 MINT

MINT [64] is a benchmark designed to evaluate agents' ability to solve challenging tasks through *multi-turn interactions* using *tools* and *natural language feedback* simulated by GPT-4. We use coding and math subsets used in Eurus [76] for evaluation. We follow the same setting as the original paper and allows the agent to interact up-to five iterations with two chances to propose solutions.

Results. As shown in Tab. 6), OpenDevin agents achieve comparable performance to the default agent in the original benchmark, with a performance improvement in the `math` subset.

Table 6: OpenDevin miscellaneous assistance evaluation results (§4.4).

Agent	Model	Success Rate (%)	$ Avg. Cost
GAIA [34], L1 validation set, 53 instances			
AutoGPT [14]	`gpt-4-turbo`	13.2	–

Human	-	21.0	–
Zero-shot Prompting [77]	`gpt-4-0314`	40.0	–
	`gpt-3.5-turbo-0613`	27.0	–
OD CodeActAgent v1.5, Generalist.	`gpt-4o-2024-05-13`	38.0	–
	`gpt-3.5-turbo-16k-0613`	24.0	–

4.4.5 ProofWriter

ProofWriter [55] is a synthetic dataset created to assess deductive reasoning abilities of LLMs. Same as Logic-LM [43], we focus on the most challenging subset, which contains 600 instances requiring 5-hop reasoning. To minimize the impact of potential errors in semantic parsing, we use the logical forms provided by Logic-LM.

Results. In Tab. 6, OpenDevin agent employs a symbolic solver to solve the task, achieving performance comparable to the *state-of-the-art* neuro-symbolic model (*i.e.*, Logic-LM) [43].

4.4.6 Entity Deduction Arena

Entity Deduction Arena (EDA) [77] evaluates agents' ability to deduce unknown entities through strategic questioning, akin to the 20 Questions game. This benchmark tests the agent's state tracking, strategic planning, and inductive reasoning capabilities over multi-turn conversations. We evaluate two datasets "Things" and "Celebrities", each comprising 100 instances, and report the average success rate over these two datasets.

Results. Tab. 6 shows that CodeActAgent yields comparable performance comparing with the results reported in the original paper [77].

5 Conclusion

We introduce OpenDevin, a community-driven platform that enables the development of agents that interact with the world through software interfaces. By providing a powerful interaction mechanism, a safe sandboxed environment, essential agent skills, multi-agent collaboration capabilities, and a comprehensive evaluation framework, OpenDevin accelerates research innovations and real-world applications of agentic AI systems. Despite challenges in developing safe and reliable agents (§A), we are excited about our vibrant community and look forward to OpenDevin's continued evolution.

Acknowledgments

We extend our heartfelt gratitude to all contributors who have made OpenDevin possible. Over 160 individuals have made more than 1,300 contributions[3], demonstrating the power of collaborative development. We are deeply appreciative of everyone[4] who has participated in discussions, raised issues, suggested improvements, and contributed code or documentation.

Author Contributions

This work was an open-source collaborative effort across multiple institutions. We employed a point-based system to determine contributions and award authorships, with technical contributions tracked and measured in units of pull requests (PRs)[5]. Xingyao Wang led the project, coordinating overall development and paper writing efforts. Detailed contributions were as follows:

- **Agent Development** (§3): Xingyao Wang led the implementation of CodeAct [63] and CodeActSWE agents. Frank F. Xu led the development of web browsing agents [79]. Mingchen Zhuge orchestrated the integration of the GPTSwarm agent [83]. Robert Brennan and Boxuan Li lead the development of the Micro Agent.
- **Architectural Development** (Fig. 3): Robert Brennan initiated the architecture design. Boxuan Li, Frank F. Xu, Xingyao Wang, Yufan Song, and Mingzhang Zheng further refined and expanded the architecture. Boxuan Li implemented the initial version of integration tests (§E), maintained the agentskills library (§2.3), managed configurations, and resolved resource leaks in evaluation. Frank F. Xu developed the web browsing environment (§I) for both agent execution and evaluation and integrated it with both agent and front-end user interfaces. Xingyao Wang authored the initial code for the agentskills library and the Docker sandbox. Yufan Song implemented cost tracking for evaluation, while Mingzhang Zheng developed an image-agnostic docker sandbox for more stable SWE-Bench evaluation.
- **Benchmarking, Integration, and Code Review**: Boxuan Li and Yufan Song led benchmark integration efforts, including coordination, evaluation, and code review. Yufan Song also helped track PR contributions. Graham Neubig, Xingyao Wang, Mingzhang Zheng, Robert Brennan, Hoang H. Tran, Frank F. Xu, Xiangru Tang, Fuqiang Li, and Yanjun Shao provided additional support in integration and code reviews. Specific benchmark contributions included:
  - SWE-Bench [21]: Bowen Li and Xingyao Wang
  - WebArena [79] and MiniWob++ [30]: Frank F. Xu
  - GAIA [34]: Jiayi Pan (integration) and Mingchen Zhuge (GPTSwarm evaluation)
  - API-Bench [46] and ToolQA [81]: Yueqi Song
  - HumanEvalFix [37]: Niklas Muennighoff and Xiangru Tang
  - ProofWriter [55]: Ren Ma
  - MINT [64]: Hoang H. Tran
  - AgentBench [31]: Fuqiang Li
  - BIRD [27]: Binyuan Hui
  - GPQA [50]: Jaskirat Singh
  - BioCoder [58]: Xiangru Tang and Bill Qian
  - ML-Bench [57]: Xiangru Tang and Yanjun Shao
  - Entity-Deduction-Arena [77]: Yizhe Zhang
- **Advising**: Graham Neubig advised the project, providing guidance, resources, and substantial paper edits. Heng Ji and Hao Peng offered additional project advice and assisted with paper writing. Junyang Lin contributed advisory support and sponsored resources.

All authors contributed to the result discussions and manuscript preparation.

A Limitations and Future Work

We are excited about the foundations our vibrant community has laid in OpenDevin and look forward to its continued evolution. We identify several directions for future work:

Enhanced multi-modality support. While our current implementation already supports a wide range of file formats through predefined agent skills, we are interested in enabling multi-modality in a principled way through standard IPython and browser integration, such as viewing images and videos using vision-language model through a browser or processing XLSX files with code.

Stronger agents. Current agents still struggle with complex tasks, and we are interested in building better agents through both training and inference time techniques.

[5]For more details, please refer to https://github.com/OpenDevin/OpenDevin/pull/1917.

Web browsing improvements. Due to the extensible nature of OpenDevin, orthogonal components that could improve agents can be integrated easily. For example, thanks to OpenDevin's extensible architecture, Auto Eval & Refine [42], an agent retry-on-error strategy with Reflexion [54] prompts and task completion reward models, will be integrated as an optional component attached to our browsing agent.

Stable Runtime. Currently, OpenDevin's default sandbox environment, SSH sandbox, relies on *pexpect* library[6] to pass commands and messages between the sandbox and agent controller. It doesn't suit other types of sandboxes (*e.g.* commercial cloud sandboxes) and is not stable enough. In the future, we plan to use EventStream as the bridge for the agent controller and the sandbox to communicate, which will be more stable, sandbox-agnostic, and enables better observability.

Automatic workflow generation. Currently, OpenDevin's workflow still requires a substantial handcrafted workload. We believe that graph-based frameworks such as GPTSwarm [83] and LangGraph [6] could serve as alternative solutions for building agents. Particularly in GPTSwarm, when agents are constructed using graphs, it becomes easier to incorporate various optimization methods (e.g., reinforcement learning, meta-prompting). OpenDevin considers these methods to lay the groundwork for promising solutions in automatic workflow generation in future versions.

B Ethics Statement

Most AI agents today are still research artifacts and lack the ability to perform complex, long-horizon tasks in the real world reliably. However, as their performance continues to improve and they are increasingly deployed in real world, they have the potential to boost productivity while also posing security risks to society significantly. OpenDevin helps mitigate risks by:

(1) Enabling systematic evaluation of these agents, which can identify and address risks before they are widely deployed.
(2) Facilitating human-agent interaction rather than allowing agents to operate autonomously without oversight.
(3) More importantly, we hope OpenDevin allows researchers worldwide to access the best suites of agents to conduct frontier safety research towards building safe and helpful agents.

C Related Work

The breakthroughs in large language models (LLMs) like ChatGPT [39] and GPT-4 [41] have significantly enhanced the capabilities of autonomous agents across various domains [10, 44, 59, 74]. These advances have spurred a multitude of generalist agent proposals [14, 38, 67] aimed at performing diverse user tasks and have gained attention from both developers and broader audiences. Notable works such as Auto-GPT [14] harness LLMs for task completion by decomposing user goals into executable steps. Multi-agent collaboration systems leverage LLMs for elements like role-playing and task-solving capabilities [26, 61, 80, 82], with MetaGPT [16] emphasizing standardized operating procedures, and AutoGen [67] providing a conversation framework for interactive systems. AGENTS [80] and AutoAgents [7] offer new paradigms for customizable agent architecture, while XAgent [61] and GPTSwarm [83] introduce complex management systems and optimizable graphs, respectively, for enhanced agent operations.

Software development, a front-runner in applying LLM-based agents, has seen advancements in frameworks for facilitating the development processes [16, 48]. Innovations such as ChatDev [48] automate the software development lifecycle akin to the waterfall model, and AutoCodeRover [78] addresses GitHub issues via code search and abstract syntax tree manipulation. AgentCoder [17] iteratively refines code generation with integrated testing and feedback, while SWE-Agent [72] integrates LLMs for automated Github issue fixing, streamlining software engineering.

[6] https://pexpect.readthedocs.io/en/stable/

D Graphical User Interface

Besides running from the command line, OpenDevin features a rich graphical user interface that visualizes the agent's current actions (*e.g.*, browsing the web, executing base commands or Python code, *etc.*) and allows for real-time feedback from the user. Screenshots of the UI are shown in Fig. 1. The user may interrupt the agent at any moment to provide additional feedback, comments, or instruction while the agent is working. This user interface directly connects with the event streams (§2.1) to control and visualize the agents and runtime, making it agent and runtime agnostic.

E Quality Control: Integration Tests for Agents

Integration tests [25] have long been used by software developers to ensure software quality. Unlike large language models with simple input-output schema, agents are typically complex pieces of software where minor errors can be easily introduced during the development process and hurt final task performance. While running a full suite evaluation (§4) is the ultimate measure of performance degradation, running them for *every* code changes can be prohibitively slow and expensive. [7]. In OpenDevin, we pioneer an end-to-end agent test framework that tests prompt regression, actions, and sandbox environments. It combines integration testing from software engineering and foundation model mocking for deterministic behavior to prevent the accidental introduction of bugs during agent development.

Defining an integration test. The integration test framework for OpenDevin is structured to validate end-to-end functionality by automating task execution and result verification. Developers define tasks and expected results; for instance, a task might involve correcting typos in a document named "bad.txt". Upon task execution through OpenDevin, outputs are compared against a predefined "gold file" to ensure accuracy.

Mocking LLM for deterministic behavior. Addressing the challenge of non-determinism in large language models (LLMs) and the associated high costs, the framework intercepts all LLM calls and supplies predefined responses based on exact prompt matches. This method not only ensures consistency in test outcomes but also reduces operational costs by minimizing the reliance on real LLMs.

Regenerate LLM responses on breaking changes. Prompt-response pairs are managed through a script that generates and stores these pairs when new tests are introduced or existing prompts are modified. For routine tests, the framework attempts to reuse existing LLM responses by slightly adjusting the prompts. Substantial changes that affect task handling require regeneration of these pairs using real LLMs.

Benefits of integration tests. The framework offers several advantages, including 1) Prompt regression testing: Stored prompt-response pairs facilitate change tracking and provide a reference for new team members to understand LLM interactions, 2) Multi-platform support: Tests are automatically scheduled for every pull request and commit on the main branch, running across multiple platforms, environments, and agents, including Linux and Mac, and in local, SSH, and exec sandboxes, and 3) Comprehensive error detection: It captures errors in prompt generation, message passing, and sandbox execution, thereby maintaining a high test coverage.

F Additional Results For GPQA Benchmark

We showcase more detailed results, including performance on other subsets for GPQA benchmark in Tab. 7.

G In-context Demonstration for CodeActSWEAgent

The prompt is re-adopted from the SWE-agent's released trajectory (https://github.com/princeton-nlp/SWE-agent/tree/main/trajectories/demonstrations). The prompt can be found at https://github.com/OpenDevin/OpenDevin/blob/main/agenthub/codeact_swe_agent/prompt.py.

[7] Running a SWE-Bench Lite [21] evaluation with `gpt-4o` costs around 600 USD.

Table 7: *Full Evaluation Results on the GPQA Benchmark [50]* (§4.4).

Evaluation Method and Model	**Accuracy by subset (%)**			**Avg Cost ($)**
	Diamond Set	*Main Set*	*Extended Set*	
Expert Human Validators	81.2	72.5	65.4	N/A
Non-Expert Human Validators	21.9	30.5	33.9	N/A
Few-Shot CoT Llama-2-70B-chat	28.1	29.1	30.4	N/A
Few-Shot CoT GPT-3.5-turbo-16k	29.6	28.0	28.2	N/A
Few-Shot CoT GPT-4	38.8	39.7	38.7	N/A
GPT-4 with search (backoff to CoT on abstention)	38.8	41.0	39.4	N/A
OpenDevin + CodeActAgent v1.5 + GPT3.5-turbo	27.9	23.4	26.1	0.012
OpenDevin + CodeActAgent v1.5 + GPT4-turbo	51.8	47.4	42.4	0.501
OpenDevin + CodeActAgent v1.5 + GPT4o	**53.1**	**49.3**	**52.8**	0.054

H Supported AgentSkills

As of OpenDevin v0.6, we support the following list of skills. Please refer to the source code for the most up-to-date list of skills: https://github.com/OpenDevin/OpenDevin/blob/main/opendevin/runtime/plugins/agent_skills/agentskills.py

```
def open_file(path: str, line_number: Optional[int] = None) -> None:
    """
    Opens the file at the given path in the editor. If line_number is
    ↪  provided, the window will be moved to include that line.

    Args:
        path: str: The path to the file to open.
        line_number: Optional[int]: The line number to move to.
    """
    pass

def goto_line(line_number: int) -> None:
    """
    Moves the window to show the specified line number.

    Args:
        line_number: int: The line number to move to.
    """
    pass

def scroll_down() -> None:
    """Moves the window down by 100 lines.

    Args:
        None
    """
    pass

def scroll_up() -> None:
    """Moves the window up by 100 lines.

    Args:
        None
    """
    pass

def create_file(filename: str) -> None:
```

```
    """Creates and opens a new file with the given name.

    Args:
        filename: str: The name of the file to create.
    """
    pass

def edit_file(start: int, end: int, content: str) -> None:
    """Edit a file.

    It replaces lines `start` through `end` (inclusive) with the given text
    ↪  `content` in the open file. Remember, the file must be open before
    ↪  editing.

    Args:
        start: int: The start line number. Must satisfy start >= 1.
        end: int: The end line number. Must satisfy start <= end <= number
        ↪  of lines in the file.
        content: str: The content to replace the lines with.
    """
    pass

def search_dir(search_term: str, dir_path: str = './') -> None:
    """Searches for search_term in all files in dir. If dir is not provided,
    ↪  searches in the current directory.

    Args:
        search_term: str: The term to search for.
        dir_path: Optional[str]: The path to the directory to search.
    """
    pass

def search_file(search_term: str, file_path: Optional[str] = None) -> None:
    """Searches for search_term in file. If file is not provided, searches
    ↪  in the current open file.

    Args:
        search_term: str: The term to search for.
        file_path: Optional[str]: The path to the file to search.
    """
    pass

def find_file(file_name: str, dir_path: str = './') -> None:
    """Finds all files with the given name in the specified directory.

    Args:
        file_name: str: The name of the file to find.
        dir_path: Optional[str]: The path to the directory to search.
    """
    pass

def parse_pdf(file_path: str) -> None:
    """Parses the content of a PDF file and prints it.

    Args:
        file_path: str: The path to the file to open.
    """
    pass
```

```python
def parse_docx(file_path: str) -> None:
    """
    Parses the content of a DOCX file and prints it.

    Args:
        file_path: str: The path to the file to open.
    """
    pass

def parse_latex(file_path: str) -> None:
    """
    Parses the content of a LaTex file and prints it.

    Args:
        file_path: str: The path to the file to open.
    """
    pass

def parse_audio(file_path: str, model: str = 'whisper-1') -> None:
    """
    Parses the content of an audio file and prints it.

    Args:
        file_path: str: The path to the audio file to transcribe.
        model: Optional[str]: The audio model to use for transcription.
        ↪  Defaults to 'whisper-1'.
    """
    pass

def parse_image(
    file_path: str, task: str = 'Describe this image as detail as
    ↪  possible.'
) -> None:
    """
    Parses the content of an image file and prints the description.

    Args:
        file_path: str: The path to the file to open.
        task: Optional[str]: The task description for the API call.
        ↪  Defaults to 'Describe this image as detail as possible.'.
    """
    pass

def parse_video(
    file_path: str,
    task: str = 'Describe this image as detail as possible.',
    frame_interval: int = 30,
) -> None:
    """
    Parses the content of an image file and prints the description.

    Args:
        file_path: str: The path to the video file to open.
        task: Optional[str]: The task description for the API call.
        ↪  Defaults to 'Describe this image as detail as possible.'.
        frame_interval: Optional[int]: The interval between frames to
        ↪  analyze. Defaults to 30.
```

```
    """
    pass

def parse_pptx(file_path: str) -> None:
    """
    Parses the content of a pptx file and prints it.

    Args:
        file_path: str: The path to the file to open.
    """
    pass
```

I BrowserGym Actions

The following are all the supported actions defined in BrowserGym[8] as of v0.3.4. The actions can be categorized into several types and can be configured to use only a subset of the functionality. There are agent control actions, navigation actions, page element-based actions, coordinate-based actions, as well as tab-related actions. We use these actions from the BrowserGym library as our main browsing action primitives.

```
def send_msg_to_user(text: str):
    """
    Sends a message to the user.

    Examples:
        send_msg_to_user("Based on the results of my search, the city was
        ↪  built in 1751.")
    """
    pass

def report_infeasible(reason: str):
    """
    Notifies the user that their instructions are infeasible.

    Examples:
        report_infeasible("I cannot follow these instructions because there
        ↪  is no email field in this form.")
    """
    pass

def noop(wait_ms: float = 1000):
    """
    Do nothing, and optionally wait for the given time (in milliseconds).

    Examples:
        noop()
        noop(500)
    """
    pass

# https://playwright.dev/docs/input#text-input

        mouse_upload_file(328, 812, ["/home/bob/Documents/image.jpg",
        ↪  "/home/bob/Documents/file.zip"])
    """
    pass
```

J Browsing Agent Details

The following shows an example prompt containing all the information required for the current step to make a prediction about the next browsing actions. Note that we also instruct the agent to predict multiple actions in one turn if the agent thinks they are meant to be executed sequentially without any feedback from the page. This could save turns for common workflows that consist of a sequence of actions on the same page without any observation change, such as filling the username and password and submit in a login page.

```
# Instructions
Review the current state of the page and all other information to find the
↪  best possible next action to accomplish your goal. Your answer will be
↪  interpreted and executed by a program, make sure to follow the
↪  formatting instructions.

# Goal:
Browse localhost:8000, and tell me the ultimate answer to life. Do not ask
↪  me for confirmation at any point.

# Action Space

16 different types of actions are available.

noop(wait_ms: float = 1000)
    Examples:
        noop()
```

```
        noop(500)

send_msg_to_user(text: str)
    Examples:
        send_msg_to_user('Based on the results of my search, the city was
        ↪  built in 1751.')

scroll(delta_x: float, delta_y: float)
    Examples:
        scroll(0, 200)

        scroll(-50.2, -100.5)

fill(bid: str, value: str)
    Examples:
        fill('237', 'example value')

        fill('45', 'multi-line\nexample')

        fill('a12', 'example with "quotes"')

select_option(bid: str, options: str | list[str])
    Examples:
        select_option('48', 'blue')

        select_option('48', ['red', 'green', 'blue'])

click(bid: str, button: Literal['left', 'middle', 'right'] = 'left',
↪  modifiers: list[typing.Literal['Alt', 'Control', 'Meta', 'Shift']] =
↪  [])
    Examples:
        click('51')

        click('b22', button='right')

        click('48', button='middle', modifiers=['Shift'])

dblclick(bid: str, button: Literal['left', 'middle', 'right'] = 'left',
↪  modifiers: list[typing.Literal['Alt', 'Control', 'Meta', 'Shift']] =
↪  [])
    Examples:
        dblclick('12')

        dblclick('ca42', button='right')

        dblclick('178', button='middle', modifiers=['Shift'])

hover(bid: str)
    Examples:
        hover('b8')

press(bid: str, key_comb: str)
    Examples:
        press('88', 'Backspace')

        press('a26', 'Control+a')

        press('a61', 'Meta+Shift+t')
```

```
focus(bid: str)
    Examples:
        focus('b455')

clear(bid: str)
    Examples:
        clear('996')

drag_and_drop(from_bid: str, to_bid: str)
    Examples:
        drag_and_drop('56', '498')

upload_file(bid: str, file: str | list[str])
    Examples:
        upload_file('572', 'my_receipt.pdf')

        upload_file('63', ['/home/bob/Documents/image.jpg',
        ↪  '/home/bob/Documents/file.zip'])

go_back()
    Examples:
        go_back()

go_forward()
    Examples:
        go_forward()

goto(url: str)
    Examples:
        goto('http://www.example.com')

Multiple actions can be provided at once. Example:
fill('a12', 'example with "quotes"')
click('51')
click('48', button='middle', modifiers=['Shift'])
Multiple actions are meant to be executed sequentially without any feedback
↪  from the page.
Don't execute multiple actions at once if you need feedback from the page.

# Current Accessibility Tree:
RootWebArea 'The Ultimate Answer', focused
        [8] heading 'The Ultimate Answer'
        [9] paragraph ''
                StaticText 'Click the button to reveal the answer to life,
                ↪  the universe, and everything.'
        [10] button 'Click me', clickable

# Previous Actions
goto('http://localhost:8000')

Here is an example with chain of thought of a valid action when clicking on
↪  a button:
"
In order to accomplish my goal I need to click on the button with bid 12
```click("12")```
```

And an example response to the above prompt is:
```

```
In order to accomplish my goal, I need to click on the button with bid 10
↪  to reveal the answer to life, the universe, and everything.
```click("10")```
```

For the evaluation on WebArena benchmark, since some of the tasks require checking for answer exact match on the agent's message back to the user, we add the following instruction to let the agent reply with only a concise answer string when messaging the user to prevent the agent from failing the test due to extra text:

```
Here is another example with chain of thought of a valid action when
↪  providing a concise answer to user:
"
In order to accomplish my goal I need to send the information asked back to
↪  the user. This page list the information of HP Inkjet Fax Machine,
↪  which is the product identified in the objective. Its price is $279.49.
↪  I will send a message back to user with the answer.
```send_msg_to_user("$279.49")```
"
```
